More particularly, the invention relates to a multiple-circuit catalytic converter of the type comprising a casing which is open towards the downstream end and comprises a multiple-circuit catalyst capable of efficiently converting the emissions produced during engine operation. Exhaust gases coming from a lean-burn engine is highly enriched with HC and NOx and contains CO. In order to avoid excessively rich exhaust gas values which may not only increase the pollution and the consumption of the engine oil, but also the NOx formation, the development of systems for the exhaust gas recirculation from the fresh gas to the lean exhaust gases, especially lean-burn engines, has been pursued since the 1970's. The inlet air/fuel ratio is reduced and the exhaust gas recirculation takes place from the downstream end to the fresh gas side, that is, from the downstream end of the lean exhaust gas to the upstream end of the exhaust gas. The exhaust gas recirculation effectively compensates the increase in fuel consumption caused by the reduced inlet air/fuel ratio, and promotes lean burn operation. On the other hand, for the very lean exhaust gas recirculation, it is essential to reduce the exhaust gas temperature, which is determined by the exhaust gas recirculation, to the temperature level of the recirc bff6bb2d33
